GND = Ground
V_{CC} = Power Supply

VCC AND GROUND PIN CONNECTIONS

CD010201

The Am29116 Family of microprocessors consists of high-performance devices that operate in an environment of fast signal rise times and substantial switching currents. Attention must be paid to layout and decoupling to avoid undesired effects from this environment. The following suggestions may be of benefit in developing the layout scheme:

1. A multi-layer PC board with separate power, ground, and signal planes required for Schottky performance-level systems.
2. Tie the four ground pins immediately to the ground plane.
3. A U-shaped isolation cut should be made in the VCC plane between pins 12 and 13 and pins 40 and 41. This isolation cut establishes a low-pass network that will provide sufficient inductive isolation between pin 40 (which supplies the TTL output drivers) and pin 41 (which supplies the internal ECL) so that transient currents will have no effect on the internal operation.
4. Pin 40 must be tied directly to the VCC plane and decoupled with a bulk capacitor (10 μF) and a high-frequency capacitor (0.1 μF ceramic).
5. Pin 41 must be tied directly to the VCC plane and decoupled with 0.1 μF and 10 μF capacitors.
6. The decoupling capacitors must be placed physically as close as possible to pin 40 and pin 41 respectively.

PIN DESCRIPTION

$Y_0 - Y_{15}$ Data I/O Lines — 16 (Input/Output)

When \overline{OE}_Y is HIGH, $Y_0 - Y_{15}$ are used as external data inputs which allow data to be directly loaded into the 16-bit data latch. Having \overline{OE}_Y LOW allows the ALU data to be output on $Y_0 - Y_{15}$.

DLE Data Latch Enable (Input)

When DLE is HIGH, the 16-bit data latch is transparent and is latched when DLE is LOW.

\overline{OE}_Y Output Enable (Input)

When \overline{OE}_Y is HIGH, the 16-bit Y outputs are disabled (high-impedance); when \overline{OE}_Y is LOW, the 16-bit Y outputs are enabled (HIGH or LOW).

$I_0 - I_{15}$ Instruction Inputs — 16 (Input)

Used to select the operations to be performed in the Am29116. Also used as data inputs while performing immediate instructions.

\overline{IEN} Instruction Enable (Input)

With \overline{IEN} LOW, data can be written into the RAM when the clock is LOW. The Accumulator can accept data during the LOW-HIGH transition of the clock. Having \overline{IEN} LOW, the Status Register can be updated when \overline{SRE} is LOW. With \overline{IEN} HIGH, the conditional test output, CT, is disabled as a function of the instruction inputs. \overline{IEN} should be LOW for the first half of the first cycle of an immediate instruction.

\overline{SRE} Status Register Enable (Input)

When \overline{SRE} and \overline{IEN} are both LOW, the Status Register is updated at the end of all instructions with the exception of

NO-OP, Save Status, and Test Status. Having either \overline{SRE} or \overline{IEN} HIGH will inhibit the Status Register from changing.

CP Clock Pulse (Input)

The clock input to the Am29116. The RAM latch is transparent when the clock is HIGH. When the clock goes LOW, the RAM output is latched. Data is written into the RAM during the low period of the clock provided \overline{IEN} is LOW and if the instruction being executed designates the RAM as the destination of operation. The Accumulator and Status Register will accept data on the LOW-HIGH transition of the clock if \overline{IEN} is also LOW. The instruction latch becomes transparent when it exits an immediate instruction mode during a LOW-HIGH transition of the clock.

$T_1 - T_4$ Input/Output Pins — 4 (Input/Output)

Under the control of OE_T , the four lower status bits Z, C, N, OVR become outputs on $T_1 - T_4$, respectively when OE_T goes HIGH. When OE_T is LOW, $T_1 - T_4$ are used as inputs to generate the CT output.

OE_T Output Enable (Input)

When OE_T is LOW, the 4-bit T outputs are disabled (high-impedance); when OE_T is HIGH, the 4-bit T outputs are enabled (HIGH or LOW).

CT Conditional Test (Output)

The condition code multiplexer selects one of the twelve condition code signals and places them on the CT output. A HIGH on the CT output indicates a passed condition and a LOW indicates a failed condition.

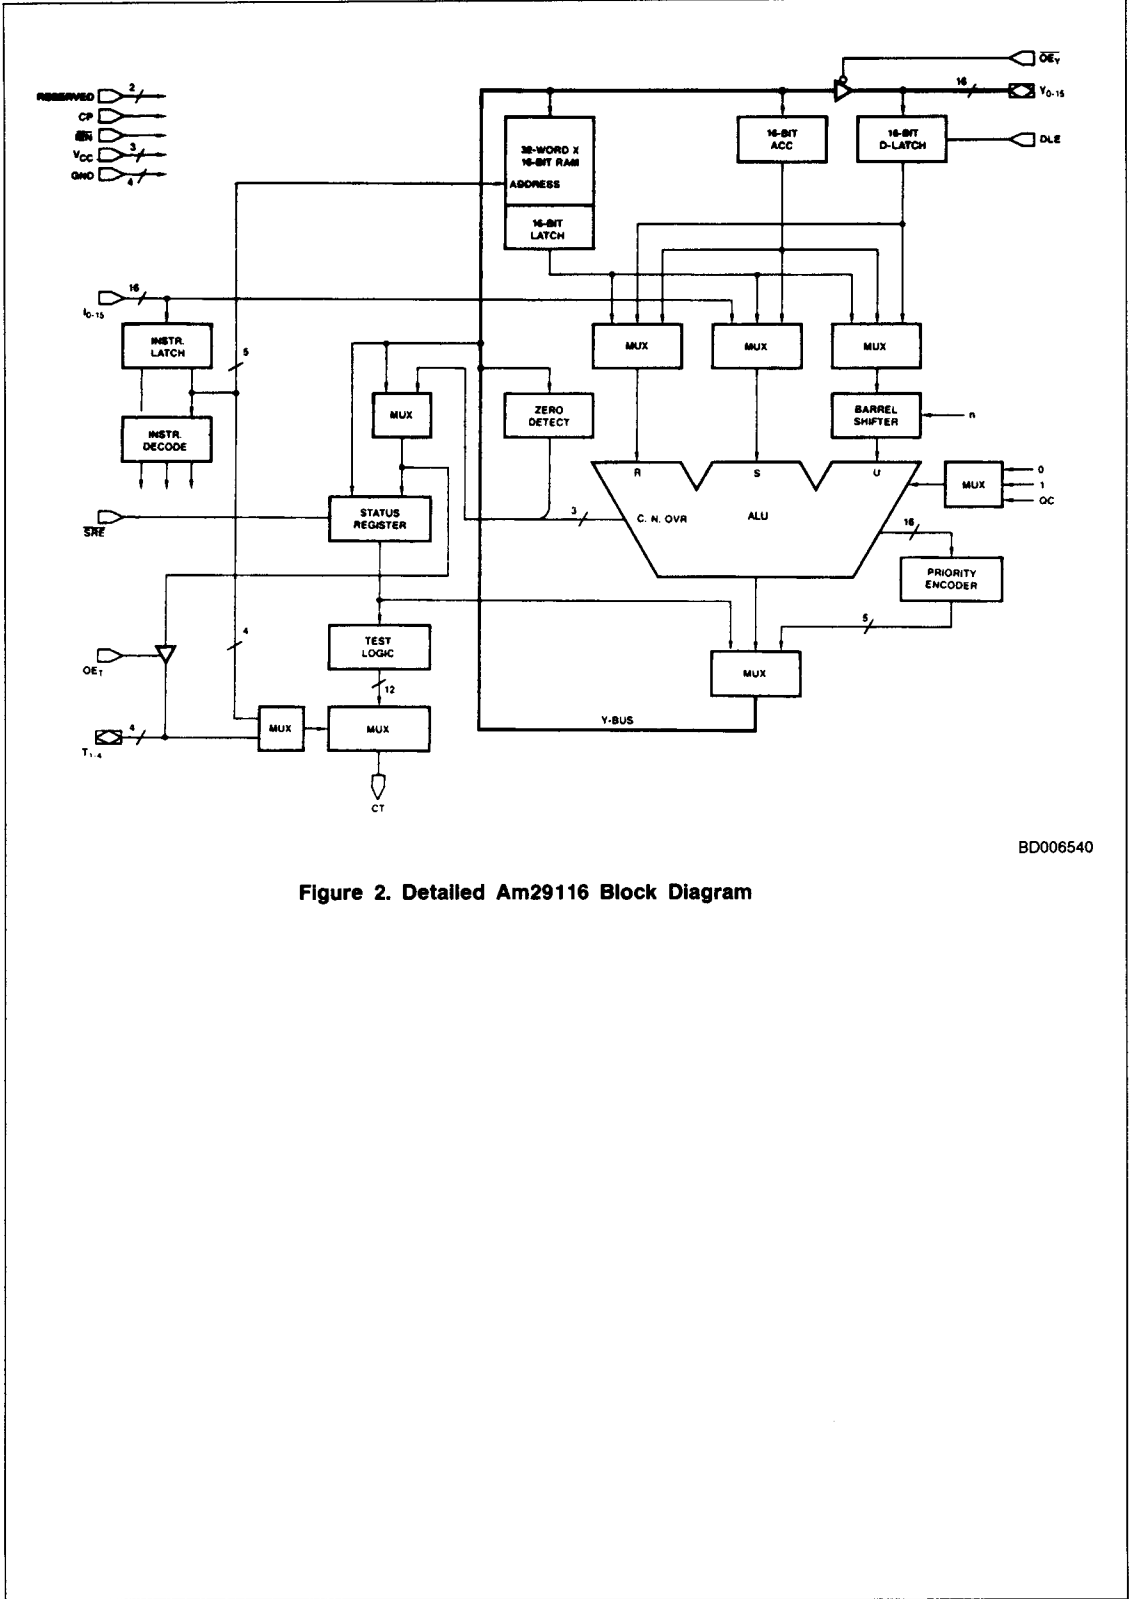

FUNCTIONAL DESCRIPTION

The following diagram (Figure 1) is a summary of devices within the Am29116 Family showing performance versus power.

OP001951

**Figure 1. Am29116 Family
(Performance Versus Power)**

BD006540

Figure 2. Detailed Am29116 Block Diagram

ARCHITECTURE OF THE Am29116

The Am29116 is a high-performance, microprogrammable 16-bit bipolar microprocessor.

As shown in the Block Diagram, the device consists of the following elements interconnected with 16-bit data paths.

- 32-Word by 16-Bit RAM
- Accumulator
- Data Latch
- Barrel Shifter
- ALU
- Priority Encoder
- Status Register
- Condition-Code Generator/Multiplexer
- Three-State Output Buffers
- Instruction Latch and Decoder

32-Word by 16-Bit RAM

The 32-Word by 16-Bit RAM is a single-port RAM with a 16-bit latch at its output. The latches are transparent when the clock input (CP) is HIGH and latched when the clock input is LOW. Data is written into the RAM while the clock is LOW if the \overline{IEN} input is also LOW and if the instruction being executed defines the RAM as the destination of the operation. For byte instructions, only the lower eight RAM bits are written into; for word instructions, all 16 bits are written into. With the use of an external multiplexer on five of the instruction inputs, it is possible to select separate read and write addresses for the same instruction. This two-address operation is not allowed for immediate instructions.

Accumulator

The 16-bit Accumulator is an edge-triggered register. The Accumulator accepts data on the LOW-to-HIGH transition of the clock input if the \overline{IEN} input is LOW and if the instruction being executed defines the Accumulator as the destination of the operation. For byte instructions, only the lower eight bits of the Accumulator are written into; for word instructions, all 16 bits are written into.

Data Latch

The 16-bit Data Latch holds the data input to the Am29116 on the bi-directional Y bus. The latch is transparent when the DLE input is HIGH and latched when the DLE input is LOW.

Barrel Shifter

A 16-bit Barrel Shifter is used as one of the ALU inputs. This permits rotating data from either the RAM, the Accumulator or the Data Latch up to 15 positions. In the word mode, the Barrel Shifter rotates a 16-bit word; in the byte mode, it rotates only the lower eight bits.

Arithmetic Logic Unit

The Am29116 contains a 16-bit ALU with full carry lookahead across all 16 bits in the arithmetic mode. The ALU is capable of operating on either one, two or three operands, depending upon the instruction being executed. It has the ability to execute all conventional one and two operand operations, such as pass, complement, two's complement, add, subtract, AND, NAND, OR, NOR, EXOR, and EX-NOR. In addition, the ALU can also execute three-operand instructions such as rotate and merge, and rotate and compare with mask. All ALU operations can be performed on either a word or byte basis, byte operations being performed on the lower eight bits only.

The ALU produces three status outputs, C (carry), N (negative) and OVR (overflow). The appropriate flags are generated at the byte or word level, depending upon whether the device is

executing in the byte or word mode. The Z (zero) flag, although not generated by the ALU, detects zero at both the byte and word level.

The carry input to the ALU is generated by the Carry Multiplexer which can select an input of zero, one, or the stored carry bit from the Status Register, QC. Using QC as the carry input allows execution of multiprecision addition and subtractions.

Priority Encoder

The Priority Encoder produces a binary-weighted code to indicate the locations of the highest order ONE at its input. The input to the Priority Encoder is generated by the ALU which performs an AND operation on the operand to be prioritized and a mask. The mask determines which bit locations to eliminate from prioritization. In the word mode, if no bit is HIGH, the output is a binary zero. If bit 15 is HIGH, the output is a binary one. Bit 14 produces a binary two, etc. Finally, if only bit 0 is HIGH, a binary 16 is produced.

In the byte mode, bits 8 thru 15 do not participate. If none of bits 7 thru 0 are HIGH, the output is a binary zero. If bit 7 is HIGH a binary one is produced. Bit 6 produces a binary two, etc. Finally, if only bit 0 is HIGH, a binary 8 is produced.

Status Register

The Status Register holds the 8-bit status word. With the Status-Register Enable, (\overline{SRE}) input LOW and the \overline{IEN} input LOW, the Status Register is updated at the end of all instructions except NO-OP, Save-Status and Test-Status instructions. \overline{SRE} going HIGH or \overline{IEN} going HIGH inhibits the Status Register from changing.

The lower four bits of the Status Register contain the ALU status bits of Zero (Z), Carry, (C) Negative (N), and Overflow (OVR). The upper four bits contain a Link bit and three user-definable status bits (Flag 1, Flag 2, Flag 3).

With \overline{SRE} LOW and \overline{IEN} LOW, the lower four status bits are updated after each instruction except those mentioned above, NO-OP, Save Status, Status Test and the Status Set/Reset instruction for the upper four bits. Under the same conditions, the upper four status bits are changed only during their respective Status Set/Reset instructions and during Status Load instructions in the word mode. The Link-Status bit is also updated after each shift instruction.

The Status Register can be loaded from the internal Y-bus, and can also be selected as a source for the internal Y-bus. When the Status Register is loaded in the word mode, all 8-bits are updated; in the byte mode, only the lower 4 bits (Z, C, N, OVR) are updated.

When the Status Register is selected as a source in the word mode, all eight bits are loaded into the lower byte of the destination; the upper byte of the destination is loaded with all zeros. In the byte mode, the Status Register again loads into the lower byte of the destination, but the upper byte remains unchanged. This Store and Load combination allows saving the restoring the Status Register for interrupt and subroutine processing. The four lower status bits (Z, C, N, OVR) can be read directly via the bidirectional T bus. These four bits are available as outputs on the $T_{1,4}$ outputs whenever OE_T is HIGH.

Condition-Code Generator/Multiplexer

The Condition-Code Generator/Multiplexer contains the logic necessary to develop the 12 condition-code test signals. The multiplexer portion can select one of these test signals and

place it on the CT output for use by the microprogram sequence. The multiplexer may be addressed in two different ways. One way is through the Test Instruction. This instruction specifies the test condition to be placed in the CT output, but does not allow an ALU operation at the same time. The second method uses the bidirectional T bus as an input. This requires extra bits in the microword, but provides the ability to simultaneously test and execute. The test instruction lines, I₀₋₄, have priority over T₁₋₄, for testing status.

Three-State Output Buffers

There are two sets of Three-State Output Buffers in the Am29116. One set controls the bidirectional, 16-bit Y bus. These outputs are enabled by placing a LOW on the \overline{OE} input. A HIGH puts the Y outputs in the high-impedance state, allowing data to be input to the Data latch from an external source.

The second set of Three-State Output Buffers controls the bidirectional 4-bit T bus and is enabled by placing a HIGH on the OE_T input. This allows storing the four internal ALU status

bits (Z, C, N, OVR) externally. A LOW OE_T input forces the T outputs into the high-impedance state. External devices can then drive the T bus to select a test condition for the CT output.

Instruction Latch and Decoder

The 16-bit Instruction Latch is normally transparent to allow decoding of the Instruction Inputs by the Instruction Decoder into the internal control signals for the Am29116. All instructions except Immediate Instructions are executed in a single clock cycle.

Immediate instructions require two clock cycles for execution. During the first clock cycle, the Instruction Decoder recognizes that an Immediate Instruction is being specified and captures the data on the Instruction Inputs in the Instruction Latch. During the second clock cycle, the data on the Instruction Inputs is used as one of the operands for the function specified during the first clock cycle. At the end of the second clock cycle, the Instruction Latch is returned to its transparent state.

INSTRUCTION SET

The instruction set of the Am29116 is very powerful. In addition to the single and two operand logical and arithmetic instructions, the Am29116 instruction set contains functions particularly useful in controller applications: bit set, bit reset, bit test, rotate and merge, rotate and compare, and cyclic-redundancy-check (CRC) generation. Complex instructions like rotate and merge, rotate and compare, and prioritize are executed in a single microcycle.

Three data types are supported by the Am29116.

- Bit
- Byte
- Word (16-bit)

In the byte mode data is written into the lower half of the word and the upper half is unchanged. The special case is when the status register is specified as the destination. In the byte mode the LSH (OVR, N, C, Z) of the status register is updated and in the word mode all eight bits of the status register are updated. The status register does not change for save status and test status instructions. In the test status instructions the CT output has the result and the Y-bus is undefined.

The Am29116 Instruction Set can be divided into eleven types of instructions. These are:

- | | |
|--------------------|---------------------------|
| ● Single Operand | ● Rotate and Compare |
| ● Two Operand | ● Prioritize |
| ● Single Bit Shift | ● Cyclic-Redundancy-Check |
| ● Rotate and Merge | ● Status |
| ● Bit Oriented | ● No-Op |
| ● Rotate by n Bits | |

Each instruction type is arbitrarily divided into quadrants. Two of the sixteen instruction lines decode to four quadrants labelled from 0 to 3. The quadrants were defined mainly for convenience in classification of the instruction set and addressing modes and can be used together with the OP CODES to distinguish the instructions.

The following pages describe each of the instruction types in detail. Throughout the description \overline{OE}_Y is assumed to be LOW allowing ALU outputs on the Y-bus.

Table 1 illustrates operand source-destination combinations for each instruction type.

TABLE 1. OPERAND SOURCE DESTINATION COMBINATIONS

Instruction Type	Operand Combinations (Note 1)		
	Source (R/S)		Destination
Single Operand	RAM (Note 2)		RAM

Flag 2			
Flag 3			

- Notes: 1. When there is no dividing line between the R&S OPERAND or SOURCE and DESTINATION, the two must be used as a given pair. But where there exists such a separation, any combination of them is possible.
2. In the SINGLE OPERAND INSTRUCTION, RAM cannot be used when both ACC and STATUS are designated as a DESTINATION.
3. In the PRIORITIZE INSTRUCTION, OPERAND and MASK must be different sources.

SINGLE OPERAND INSTRUCTIONS

The Single Operand Instructions contain four indicators: byte or word mode, opcode, source and destination. They are further subdivided into two types. The first type uses RAM as a source or destination or both, and the second type does not use RAM as a source or destination. Both types have different instruction formats as shown below. Under the control of instruction inputs, the desired function is performed on the source and the result is either stored in the specified destination or placed on the Y-bus or both. For a special case where

8-bit to 16-bit conversion is needed, the Am29116 is capable of extending sign bit (D(SE)) or binary zero (D(0E)) over 16-bits in the word mode. The least significant four bits of the Status Register (OVR, N, C, Z) are affected by the function performed in this category. The most significant bits of status register (FLAG1, FLAG2, FLAG3, LINK) are not affected. The only limitation in this type is that the RAM cannot be used as a source when both ACC and the Status Register are specified as a destination.

SINGLE OPERAND FIELD DEFINITIONS

SRC = Source
 U = Update
 NC = No Change

0 = Reset
 1 = Set
 i = 0 to 15 when not specified

TWO OPERAND INSTRUCTIONS

The Two Operand Instructions contain five indicators: byte or word mode, opcode, R source, S source, and destination. They are further subdivided into two types. The first type uses RAM as the source and/or destination and the second type does not use RAM as source or destination. The first type has two formats; the only difference is in the quadrant. Under the control of instruction inputs, the desired function is performed on the specified sources and the result is stored in the

specified destination or placed on the Y-bus or both. The least significant four bits of the status register (OVR, N, C, Z) are affected by the arithmetic functions performed and only the N and Z bits are affected by the logical functions performed. The OVR and C bits of the status register are forced to ZERO for logical functions. Add with carry and Subtract with carry instructions are useful for Multiprecision Add or Subtract.

SINGLE BIT SHIFT INSTRUCTIONS

The Single Bit Shift Instructions contain four indicators: byte or word mode, direction and shift linkage, source and destination. They are further subdivided into two types. The first type uses RAM as the source and/or destination and the second type does not use RAM as source or destination. Under the control of the instruction inputs, the desired shift function is performed on the specified source and the result is stored in the specified destination or placed on the Y-bus or both. The direction and shift linkage indicator defines the direction of the shift (up or down) as well as what will be shifted into the vacant bit. On a shift-up instruction, the LSB may be loaded with ZERO, ONE,

or the Link-Status bit (QLINK). The MSB is loaded into the Link-Status bit as shown in Figure 3. On a shift-down instruction, the MSB may be loaded with ZERO, ONE, the contents of the Status Carry flip-flop, (QC), the Exclusive-OR of the Negative-Status bit and the Overflow-Status bit (QN ⊕ QOVR) or the Link-Status bit. The LSB is loaded into the Link-Status bit as shown in Figure 4. The N and Z bits of the Status register are affected but the OVR and C bits are forced to ZERO. The Shift-Down with QN ⊕ QOVR is useful for Two's Complement multiplication.

BIT ORIENTED INSTRUCTIONS

The Bit Oriented Instructions contain four indicators: byte or word mode, operation, source/destination, and the bit position of the bit to be operated on (Bit 0 is the least significant bit). They are further subdivided into two types. The first type uses the RAM as both source and destination and has two kinds of formats which differ only by quadrant. The second type does not use the RAM as a source or a destination. Under the control of the instruction inputs, the desired function is performed on the specified source and the result is stored in the specified destination or placed on the Y-bus or both. The operations which can be performed are: Set Bit n which forces the n^{th} bit to a ONE leaving other bits unchanged; Reset Bit n

which forces the n^{th} bit to ZERO leaving the other bits unchanged; Test Bit n, which sets the ZERO Status Bit depending on the state of bit n leaving all the bits unchanged; Load 2^n , which loads ONE in Bit position n and ZERO in all other bit positions; Load $\overline{2^n}$ which loads ZERO in bit position n and ONE in all other bit positions; increment by 2^n , which adds 2^n to the operand; and decrement by 2^n which subtracts 2^n from the operand. For all the Load, Set, Reset and Test instructions, the N and Z bits are affected and OVR and C bit of the Status register are forced to ZERO. For all arithmetic instructions the LSH (OVR, C, N, Z bits) of the Status register is affected.

ROTATE BY n BITS INSTRUCTIONS

The Rotate by n Bits Instructions contain four indicators: byte or word mode, source, destination and the number of places the source is to be rotated. They are further subdivided into two types. The first type uses RAM as a source and/or a destination and the second type does not use RAM as a source or destination. The first type has two different formats and the only difference is in the quadrant. The second type has only one format as shown in the table. Under the control of instruction inputs, the n indicator specifies the number of bit positions the source is to be rotated up (0 to 15), and the result

is either stored in the specified destination or placed on the Y-bus or both. An example of this instruction is given in Figure 5. In the Word mode, all 16-bits are rotated up while in the Byte mode, only the lower 8-bits (0-7) are rotated up; In the Word mode, a rotate up by n bits is equivalent to a rotate down by (16-n) bits. Similarly, in the Byte mode a rotate up by n bits is equivalent to a rotate down by (8-n) bits. The N and Z bits of the Status Register are affected and OVR and C bits are forced to ZERO.

EXAMPLE: n = 4, Word Mode

ROTATE AND MERGE INSTRUCTION

The Rotate and Merge Instructions contain five indicators: byte or word mode, rotated source, non-rotated source/destination, mask and the number of bit positions a source is to be rotated. The function performed by the Rotate and Merge instruction is illustrated in Figure 6. The rotated source, U, is rotated up by the Barrel Shifter n places. The mask input then selects, on a bit by bit basis, the rotated U input or R

input. A ZERO in bit i of the mask will select the i^{th} bit of the R input as the i^{th} output bit, while ONE in bit i will select the i^{th} rotated U input as the output bit. The output word is stored in the non-rotated operand location. The N and Z bits are affected. The OVR and C bits of the Status register are forced to ZERO. An example of this instruction is given in Figure 7.

ROTATE AND COMPARE INSTRUCTIONS

The Rotate and Compare Instructions contain five indicators: byte or word mode, rotated source, non-rotated source, mask, and the number of bit positions the rotated source is to be rotated up. Under the control of instruction inputs, the function performed by the Rotate and Compare instruction is illustrated in Figure 8. The rotated operand is rotated by the Barrel Shifter n places. The mask is inverted and ANDed on a bit-by-bit basis

with the output of the Barrel Shifter and R input. Thus, a ONE in the mask input eliminates that bit from the comparison. A ZERO allows the comparison. If the comparison passes, the Zero flag is set. If it fails, the Zero flag is reset. The N and Z bit are affected. The OVR and C bits of the Status register are forced to ZERO. An example of this instruction is given in Figure 9.

PRIORITIZE INSTRUCTION

The Prioritize Instructions contain four indicators: byte or word mode, operand source (R), mask source (S) and destination. They are further subdivided into two types. The function performed by the Prioritize instruction is shown in Figure 10. The R operand is ANDed with the complement of the Mask operand. A ZERO in the Mask operand allows the corresponding bit in the R operand to participate in the priority encoding function. A ONE in the Mask operand forces the corresponding bit in the R operand to a ZERO, eliminating it from participation in the priority encoding function.

The priority encoder accepts a 16-bit input and produces a 5-bit binary-weighted code indicating the bit position of the highest priority active bit. If none of the inputs are active, the output is ZERO. In the Word mode, if input bit 15 is active, the output is 1, etc. Figure 11 lists the output as a function of the highest-priority active-bit position in both the Word and Byte mode. The N and Z bits are affected and the OVR and C bits of the status register are forced to ZERO. The only limitation in this instruction is that the operand and the mask must be from different sources.

CRC INSTRUCTION

The CRC (Cyclic-Redundancy-Check) Instructions contain one indicator: address of a RAM register to use as the check sum register. The CRC instruction provides a method for generation of the check bits in a CRC calculation. Two CRC instructions are provided - CRC Forward and CRC Reverse. The reason for providing two instructions is that CRC standards do not specify which data bit is to be transmitted first, the LSB or the MSB, but they do specify which check bit must be transmitted first. Figure 12 illustrates the method used to generate these check bits for the CRC Forward function and

Figure 13 illustrates method used for the 2CRC Reverse function. The ACC serves as a polynomial mask to define the generating polynomial while the RAM register holds the partial result and eventually the calculated check sum. The LINK-bit is used as the serial input. The serial input combines with the MSB of the check-sum register, according to the polynomial defined by the polynomial mask register. When the last input bit has been processed, the check-sum register contains the CRC check bits. The LINK, N and Z bits are affected and the OVR and C bits of the Status register are forced to ZERO.

CYCLIC-REDUNDANCY-CHECK DEFINITIONS:

	15	14	13	12	9	8	5	4	0
CRCF	1	Quad	0110	0011	RAM Address				
CRCR	1	Quad	0110	1001	RAM Address

Y BUS AND STATUS - CYCLIC REDUNDANCY CHECK

Instruction	Opcode	B/W	Y - Bus	Flag3	Flag2	Flag1	LINK	OVR	N	C	Z
CRCF		1 = W	$Y_i = [(QLINK \oplus RAM_{15}) \cdot ACC_i]$ $\oplus RAM_{i-1} \text{ for } i = 15 \text{ to } 1$ $Y_0 = [(QLINK \oplus RAM_{15}) \cdot ACC_0] \oplus 0$	NC	NC	NC	RAM ₁₅ *	0	U	0	U
CRCR		1 = W	$Y_i = [(QLINK \oplus RAM_0) \cdot ACC_i]$ $\oplus RAM_{i+1} \text{ for } i = 14 \text{ to } 0$ $Y_{15} = [(QLINK \oplus RAM_0) \cdot ACC_{15}] \oplus 0$	NC	NC	NC	RAM ₀ *	0	U	0	U

*QLINK is loaded with the shifted out bit from the checksum register.

U = Update
 NC = No Change
 0 = Reset
 1 = Set
 i = 0 to 15 when not specified

STATUS INSTRUCTIONS

Status Instructions - The Set Status Instruction contains a single indicator. This indicator specifies which bit or group of bits, contained in the status register (Figure 14), are to be set (forced to a ONE).

MPR-775

Figure 14. Status Byte.

The Reset Status Instruction contains a single indicator. This indicator specifies which bit or group of bits, contained in the status register, are to be reset (forced to ZERO).

The Store Status Instruction contains two indicators; byte/word and a second indicator that specifies the destination of the status register. The Store Status Instruction allows the status of the processor to be saved and restored later, which is an especially useful function for interrupt handling.

The status register is always stored in the lower byte of the RAM or the ACC register. Depending upon byte or word mode the upper byte is unchanged or loaded with all ZEROS respectively.

The Load Status instructions are included in the single operand and two operand instruction types.

The Test Status Instructions contain a single indicator which specifies which one of the 12 possible test conditions are to be placed on the Conditional-Test output. Besides the eight bits in the Status register (QZ, QC, QN, QOVR, QLINK, QFlag1, QFlag 2, and QFlag3), four logical functions (QN ⊕ QOVR), (QN ⊕ QOVR) + QZ, QZ + QC and LOW may also be selected. These functions are useful in testing results of Two's Complement and unsigned number arithmetic operations. The status register may also be tested via the bidirectional T bus. The code to test the status register via T bus is similar to the code used by instruction lines I₁ to I₄ as shown below. Instruction lines I₀ - 4 have priority over T bus for testing the

status register on CT output. See the discussion on the status register for a full description.

T ₄ I ₄	T ₃ I ₃	T ₂ I ₂	T ₁ I ₁	CT
0	0	0	0	(N ⊕ OVR) + Z
0	0	0	1	N ⊕ OVR
0	0	1	0	Z
0	0	1	1	OVR
0	1	0	0	LOW*
0	1	0	1	C
0	1	1	0	Z + C̄
0	1	1	1	N
1	0	0	0	LINK
1	0	0	1	Flag1
1	0	1	0	Flag2
1	0	1	1	Flag3

*LOW means CT is forced LOW

ROTNR	Rotate n Bits Non-RAM
BOR1	Bit Oriented RAM (Quad 3)
BOR2	Bit Oriented RAM (Quad 2)
BONR	Bit Oriented Non-RAM
ROTM	Rotate and Merge
ROTC	Rotate and Compare
PRT1	Prioritize RAM; Type 1
PRT2	Prioritize RAM; Type 2
PRT3	Prioritize RAM; Type 3
PRTNR	Prioritize Non-RAM
CRCF	Cyclic Redundancy Check Forward
CRCR	Cyclic Redundancy Check Reverse
NOOP	No Operation
SETST	Set Status
RSTST	Reset Status
SVSTR	Save Status RAM
SVSTNR	Save Status Non-RAM
TEST	Test Status

SOURCE AND DESTINATION

Single Operand

SORA	Single Operand RAM to ACC
SORY	Single Operand RAM to Y Bus
SORS	Single Operand RAM to Status
SOAR	Single Operand ACC to RAM
SODR	Single Operand D to RAM
SOIR	Single Operand I to RAM
SOZR	Single Operand 0 to RAM
SOZER	Single Operand D(0E) to RAM
SOSER	Single Operand D(SE) to RAM
SORR	Single Operand RAM to RAM
SOA	Single Operand ACC
SOD	Single Operand D
SOI	Single Operand I
SOZ	Single Operand 0
SOZE	Single Operand D(0E)
SOSE	Single Operand D(SE)
NRV	Non-RAM Y Bus
NRA	Non-RAM ACC
NRS	Non-RAM Status
NRAS	Non-RAM ACC, Status

Two Operand

TORAA	Two Operand RAM, ACC to ACC
TORIA	Two Operand RAM, I to ACC
TODRA	Two Operand D, RAM to ACC
TORAY	Two Operand RAM, ACC to Y Bus
TORIY	Two Operand RAM, I to Y Bus
TODRY	Two Operand D, RAM to Y Bus
TORAR	Two Operand RAM, ACC to RAM
TORIR	Two Operand RAM, I to RAM
TODRR	Two Operand D, RAM to RAM
TODAR	Two Operand D, ACC to RAM
TOAIR	Two Operand ACC, I to RAM
TODIR	Two Operand D, I to RAM
TODA	Two Operand D, ACC
TOAI	Two Operand ACC, I
TODI	Two Operand D, I

Single Bit Shift

SHRR	Shift RAM, Store in RAM
SHDR	Shift D, Store in RAM
SHA	Shift ACC
SHD	Shift D

Rotate n Bits

RTRA	Rotate RAM, Store in ACC
RTRY	Rotate RAM, Place on Y Bus
RTRR	Rotate RAM, Store in RAM
RTAR	Rotate ACC, Store in RAM
RTDR	Rotate D, Store in RAM
RTDY	Rotate D, Place on Y Bus
RTDA	Rotate D, Store in ACC
RTAY	Rotate ACC, Place on Y Bus
RTAA	Rotate ACC, Store in ACC

Rotate and Merge

MDAI	Merge Disjoint Bits of D and ACC Using I as Mask and Store in ACC
MDAR	Merge Disjoint Bits of D and ACC Using RAM as Mask and Store in ACC
MDRI	Merge Disjoint Bits of D and RAM Using I as Mask and Store in RAM
MDRA	Merge Disjoint Bits of D and RAM Using ACC as Mask and Store in RAM
MARI	Merge Disjoint Bits of ACC and RAM Using I as Mask and Store in RAM
MRAI	Merge Disjoint Bits of RAM and ACC Using I as Mask and Store in ACC

Rotate and Compare

CDAI	Compare Unmasked Bits of D and ACC Using I as Mask
------	--

CDRI Compare Unmasked Bits of D and RAM Using I as Mask
 CDRA Compare Unmasked Bits of D and RAM Using ACC as Mask
 CRAI Compare Unmasked Bits of RAM and ACC Using I as Mask

Prioritize

PR1A ACC as Destination for Prioritize Type 1
 PR1Y Y Bus as Destination for Prioritize Type 1
 PR1R RAM as Destination for Prioritize Type 1
 PRT1A ACC as Source for Prioritize Type 1
 PR1D D as Source for Prioritize Type 1
 PR2A ACC as Destination for Prioritize Type 2
 PR2Y Y Bus as Destination for Prioritize Type 2
 PR3R RAM as Source for Prioritize Type 3
 PR3A ACC as Source for Prioritize Type 3
 PR3D D as Source for Prioritize Type 3
 PRTA ACC as source for Prioritize Type Non-RAM
 PRTD D as Source for Prioritize Type Non-RAM
 PRA ACC as Mask for Prioritize Type 2, 3, and Non-RAM
 PRZ Mask Equal to Zero for Prioritize Type 2, 3, and Non-RAM
 PRI I as Mask for Prioritize Type 2, 3, and Non-RAM

OPCODE

Addition

ADD Add without Carry
 ADDC Add with Carry
 A2NA Add 2^n to ACC
 A2NR Add 2^n to RAM
 A2NDY Add 2^n to D, Place on Y Bus

Subtraction

SUBR Subtract R from S without Carry
 SUBRC Subtract R from S with Carry
 SUBS Subtract S from R without Carry
 SUBSC Subtract S from R with Carry
 S2NR Subtract 2^n from RAM
 S2NA Subtract 2^n from ACC
 S2NDY Subtract 2^n from D, Place on Y Bus

Logical Operations

AND Boolean AND
 NAND Boolean NAND
 EXOR Boolean EXOR
 NOR Boolean NOR
 OR Boolean OR
 EXNOR Boolean EXNOR

SHIFTS

SHUPZ Shift Up Towards MSB with 0 Insert
 SHUP1 Shift Up Towards MSB with 1 Insert
 SHUPL Shift Up Towards MSB with LINK Insert

SHDNZ Shift Down Towards LSB with 0 Insert
 SHDN1 Shift Down Towards LSB with 1 Insert
 SHDNL Shift Down Towards LSB with LINK Insert
 SHDNC Shift Down Towards LSB with Carry Insert
 SHDNOV Shift Down Towards LSB with Sign EXOR Overflow Insert

Loads

LD2NR Load 2^n into RAM
 LDC2NR Load 2^n into RAM
 LD2NA Load 2^n into ACC
 LDC2NA Load 2^n into ACC
 LD2NY Place 2^n on Y Bus
 LDC2NY Place 2^n on Y Bus

Bit Oriented

SETNR Set RAM, Bit n
 SETNA Set ACC, Bit n
 SETND Set D, Bit n
 SONGZ Set OVR, N, C, Z, in Status Register
 SL Set LINK Bit in Status Register
 SF1 Set Flag1 Bit in Status Register
 SF2 Set Flag2 Bit in Status Register
 SF3 Set Flag3 Bit in Status Register
 RSTNR Reset RAM, Bit n
 RSTNA Reset ACC, Bit n
 RSTND Reset D, Bit n
 RONCZ Reset OVR, N, C, Z, in Status Register
 RL Reset LINK Bit in Status Register
 RF1 Reset Flag1 Bit in Status Register
 RF2 Reset Flag2 Bit in Status Register
 RF3 Reset Flag3 Bit in Status Register
 TSTNR Test RAM, Bit n
 TSTNA Test ACC, Bit n
 TSTND Test D, Bit n

Arithmetic Operations

MOVE Move and Update Status
 COMP Complement (1's Complement)
 INC Increment
 NEG Two's Complement

Conditional Test

TNOZ Test $(N \oplus OVR) + Z$
 TNO Test $N \oplus OVR$
 TZ Test Zero Bit
 TOVR Test Overflow Bit
 TLOW Test for LOW
 TC Test Carry Bit
 TZC Test $Z + \bar{C}$
 TN Test Negative Bit
 TL Test LINK Bit
 TF1 Test Flag1 Bit
 TF2 Test Flag2 Bit
 TF3 Test Flag3 Bit

ABSOLUTE MAXIMUM RATINGS

Storage Temperature -65 to +150°C
 (Case) Temperature Under Bias -55 to +125°C
 Supply Voltage to Ground Potential -0.5 V to +7.0 V
 DC Voltage Applied to Outputs For
 High Output State -0.5 V to +V_{CC} Max.
 DC Input Voltage -0.5 V to +5.5 V
 DC Output Current, Into Outputs 30 mA
 DC Input Current -30 mA to +5.0 mA

Stresses above those listed under ABSOLUTE MAXIMUM RATINGS may cause permanent device failure. Functionality at or above these limits is not implied. Exposure to absolute maximum ratings for extended periods may affect device reliability.

OPERATING RANGES

Commercial (C) Devices
 Temperature (T_A) 0 to +70°C
 Supply Voltage +4.75 V to +5.25 V

Military (M) Devices
 Temperature (T_C) -55 to +125°C
 Supply Voltage +4.5 V to +5.5 V

Operating ranges define those limits between which the functionality of the device is guaranteed.

DC CHARACTERISTICS over operating range unless otherwise specified; All APL and CPL products are included in Group A, Subgroup 1, 2, 3 tests unless otherwise noted.

				T _A = 70°C		400	
				T _C = -55 to 125°C (Note 7)		745	
			MIL (Am29116 only)	T _C = 125°C		525	

- Notes: 1. Typical limits are at V_{CC} = 5.0 V, 25°C ambient and maximum loading.
 2. For conditions shown as Min. or Max., use the appropriate value specified under Operating Ranges for the applicable device type.
 3. Not more than one output should be shorted at a time. Duration of the short circuit test should not exceed one second.
 4. Y₀₋₁₅, T₁₋₄ are three-state outputs internally connected to TTL inputs. Input characteristics are measured under conditions such that the outputs are in the OFF state.
 5. Worst case I_{CC} is at minimum temperature.
 6. These input levels provide zero noise immunity and should be tested only in a static, noise-free environment.
 7. Cold start.

Test Philosophy and Methods

The following points give the general philosophy that we apply to tests that must be properly engineered if they are to be implemented in an automatic testing environment. The specifics of what philosophies are applied to which test are shown in the data sheet and the data-sheet reconciliation that follow.

Capacitive Loading for AC Testing

Automatic testers and their associated hardware have stray capacitance that varies from one type of tester to another, but is generally around 50 pF. This, of course, makes it impossible to make direct measurements of parameters that call for smaller capacitive load than the associated stray capacitance. Typical examples of this are the so-called "float delays" that measure the propagation delays in to and out of the high-impedance state and are usually specified at a load capacitance of 5.0 pF. In these cases, the test is performed at the higher load capacitance (typically 50 pF) and engineering correlations based on data taken with a bench setup are used to determine the result at the lower capacitance.

Similarly, a product may be specified at more than one capacitive load. Since the typical automatic tester is not capable of switching loads in mid-test, it is impractical to make measurements at both capacitances even though they may both be greater than the stray capacitance. In these cases, a measurement is made at one of the two capacitances. The result at the other capacitance is determined from engineering correlations based on data taken with a bench setup and the knowledge that certain DC tests are performed in order to facilitate this correlation.

AC loads specified in the data sheet are used for bench testing. Automatic tester loads, which simulate the data-sheet loads, may be used during production testing.

Threshold Testing

The noise associated with automatic testing, the long inductive cables, and the high gain of bipolar devices frequently give rise to oscillations when testing high-speed circuits. These oscillations are not indicative of a reject device, but instead, of an overtaxed system. To minimize this problem, thresholds are tested at least once for each input pin. Thereafter, "hard" high and low levels are used for other tests. Generally this means that function and AC testing are performed at "hard" input levels.

AC Testing

AC parameters are specified that cannot be measured accurately on automatic testers because of tester limitations. Data-input hold times fall into this category. In these cases, the parameter in question is tested by correlating the tester to bench data or oscilloscope measurements made on the tester by engineering (supporting data on file).

Certain AC tests are redundant since they can be shown to be predicted by other tests that have already been performed. In these cases, the redundant tests are not performed.

Output Short-Circuit Current Testing

When performing I_{OS} tests on devices containing RAM or registers, great care must be taken that undershoot caused by grounding the high-state output does not trigger parasitic elements which in turn cause the device to change state. In order to avoid this effect, it is common to make the measurement at a voltage (V_{output}) that is slightly above ground. The V_{CC} is raised by the same amount so that the result (as confirmed by Ohm's law and precise bench testing) is identical to the $V_{OUT} = 0, V_{CC} = Max.$ case.

Am29116A System Cycle Times

SYSTEM BLOCK DIAGRAM

BD005950

DATA PATH TIMING ANALYSIS

I. Without Any External Logic

a.	Pipeline Register (29821)	CP-Q	12 ns
	RALU (29116A)	I-T ₁₋₄	60
	Status Register (29821)	Setup	4
	Cycle Time:		76 ns
b.	Pipeline Register (29821)	CP-Q	12 ns
	RALU (29116A)	I-Y	53
	Data Register (29821)	Setup	4
	Cycle Time:		69 ns

II. With Multiplexers for Address, N-Count, etc.

a.	Pipeline Register (29821)	CP-Q	12 ns
	Multiplexer (F157)	Sel-Y	15
	RALU (29116A)	I-T ₁₋₄	60
	Status Register (29821)	Setup	4
	Cycle Time:		91 ns
b.	Pipeline Register (29821)	CP-Q	12 ns
	Multiplexer (F157)	Sel-Y	15
	RALU (29116A)	I-Y	53
	Data Register (29821)	Setup	4
	Cycle Time:		84 ns

III. Using Y-Bus as Input/Output in One Cycle

a.	Pipeline Register (29821)	CP-Q	12 ns
	Decoder (2924)	Sel-Y	12
	Source Select (29821)	OE-Y	15
	RALU (29116A)	Y _{IN} - Y _{OUT}	39
	Destination (29821)	Setup	4
	Cycle Time:		82 ns

DLE can go LOW 6 ns (Y to DLE Setup) after data is valid on Y-bus (i.e., 45 ns after CP ↑). OE_Y should go LOW before 68 ns (OE_Y Enable is 22 ns) from CP ↑. Therefore a 50% duty cycle will work at 90 ns with DLE tied to OE_Y to CP.

CONTROL PATH TIMING ANALYSIS

* For the Am29112 Instruction 18 (Test SP with D (TSTSP.P)) is not used. If Instruction 18 is used D-Y is 35 ns and I-Y is 47 ns.

**For the Am29112 Relative Branch Instructions are not used. If the Relative Branch Instructions are used D-Y is 43 ns.

THE USE OF AN EXTERNAL STATUS REGISTER IN REDUCING MICROCYCLE LENGTH

The standard connection of the CT pin of the Am29116 and microcycle length calculation arising from that connection are shown below:

CRITICAL PATH TIMING (FIGURE A)

Part Number	Path	Maximum Commercial Delay (ns)
Pipeline Register	CP-Q	12
Am29116A	i, T-CT	29
Am2923 CC-MUX	D-W	7
74S86 Polarity	D-Y	11
Am2910A	CC-Y	30
Control Memory	tAA	40
Pipeline Register	Setup	4
		133

While 133 ns cycle time is quite fast, it can be improved by using an external register for status testing.

CRITICAL PATH TIMING (FIGURE B)

Part Number	Path	Maximum Commercial Delay (ns)
Am29821 Status Reg	CP-Y	12
Am2923 CC-MUX	Set-W	15
74S86 Polarity	D-Y	11
Am2910A	CC-Y	30
Control Memory	tAA	40
Pipeline Register	Setup	4
		112

The cycle time has been reduced from 133 ns to 112 ns.
